Case: The hosting lost the CRM server. I restored the portal from a backup.

Nikita, DevOps engineer
Real case from my work. Client name hidden.

Business	A company works in self-hosted Bitrix24: CRM, chats with customers, business processes.
Risk	The portal server was at the hosting provider Beget. On 3 Nov 2026 it was gone. For more than a week Beget says nothing about the data.
My work	Nightly backups with a weekly restore check, a new server in Yandex Cloud as code, restore.
Result	The data of 2 Nov is on a new server. The restore took 34 minutes.

The business risk

- The client kept the portal server at the hosting provider Beget. On 2 Nov 2026 Beget had a large outage.
- On 3 Nov the nightly backup could not connect to the client server. The server did not answer at all.
- For more than a week Beget says nothing about the data on this server. Most likely, the data is lost.
- The full portal worked on this server: CRM, chats with customers, tasks and business processes.
- Without its own copy, the company would lose all its history of work with customers.

What I did

- In September I built a backup system. Every night it takes the database and files of the portal to a separate server outside Beget.
- Once a week the system checks the backup by itself. On 8 Nov the check confirmed: the backup of 2 Nov can be restored, the database has 1768 tables.
- On 9 Nov I wrote the new server as Terraform code and created it in Yandex Cloud in 41 seconds.
- I wrote the Bitrix server setup as Ansible code. I found and went around a bug of the official installer.
- During the copy, the network card of the office backup server failed. From a console photo I found the cause and made the fix permanent.

- I ran the restore as a separate service. A VPN or SSH drop does not stop it.

2 Nov, 01:00
last backup

3 Nov
server at Beget is gone

8 Nov
backup checked: 1768 tables

9 Nov
new server, restore in 34 min

Result

- **The backup saved the data: Beget cannot return it for more than a week, but the client has its own copy of 2 Nov.**
- **5.4 GB of files and the portal database are on the new server. The restore took 34 minutes.**
- **The domain moved to the new server on the same day.**
- **The new server, its setup and the restore are code. A repeat move is a few commands.**
- **A hidden fault of the office backup server was found and fixed.**

More results from my work

> **The website went down at night - cause found in 20 minutes**
>
> The same night, on 2 Nov at 02:41, a site of another client at Beget went down. The alert came after 5 minutes. In the morning, 20 minutes of checks proved: the outage was at Beget, not in our setup.

> **The GitLab server stopped 4 times in 2 months**
>
> In the host logs I found the cause: the host gave its virtual machines almost twice more memory than it had. I cut the memory, added a compressed swap and closed the control panel from password attacks.

How the result looks

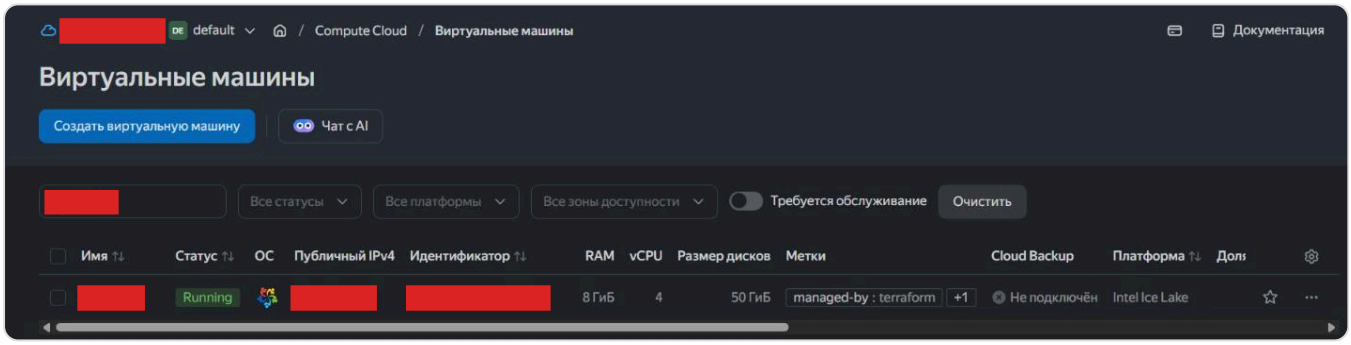

bxbackup — сервер бэкапов

```
$ bxbackup snapshots [redacted] | tail -3
4582a6bb  2026-11-02 01:02:22  db        /db.sql
1ec13826  2026-11-02 01:04:20  files     /srv/backup/mirror/[redacted]/www
e2e21bc5  2026-11-02 01:04:52  sysconf   /sysconf.tar

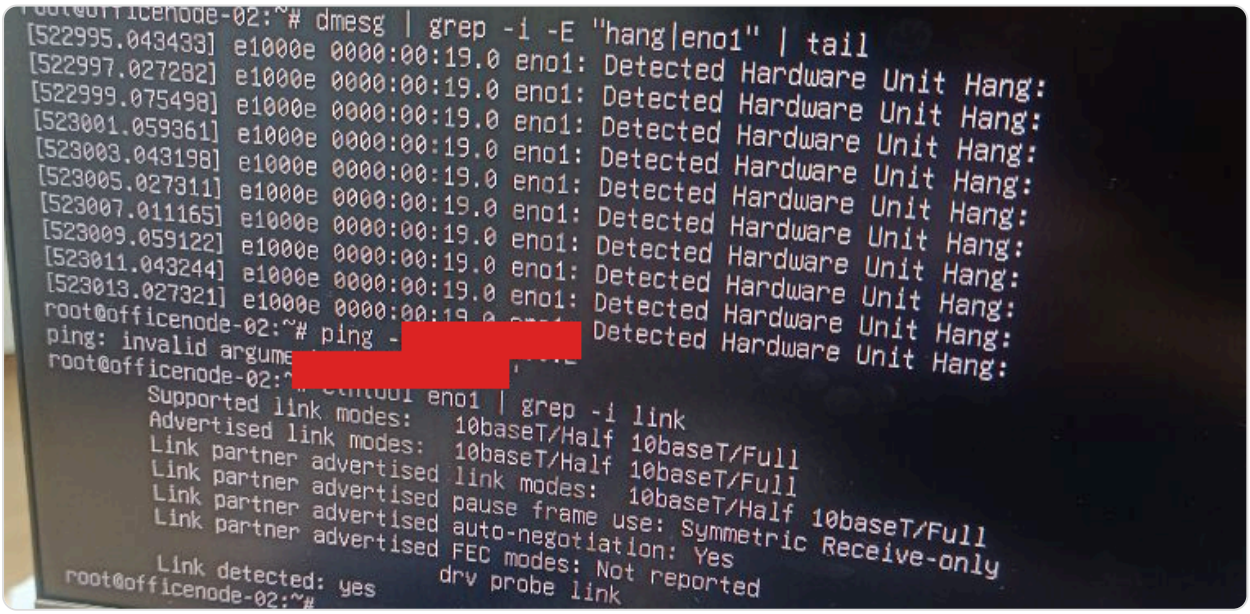

$ journalctl -u bxbackup-run --since 2026-11-03 | grep [redacted]
Nov 03 01:02:44  ssh: connect to host [redacted] port 22: Connection timed out
Nov 03 01:03:46  [redacted] бэкап завершён: С ОШИБКАМИ

$ journalctl -u bxbackup-verify --since 2026-11-08
Nov 08 06:29:24  [redacted] verify: restic check (--read-data-subset=5%)
Nov 08 06:29:37  [redacted] verify: восстановление дампа 4582a6bb (2026-11-02 01:02)
Nov 08 07:15:48  [redacted] verify: OK (1768 таблиц)
```

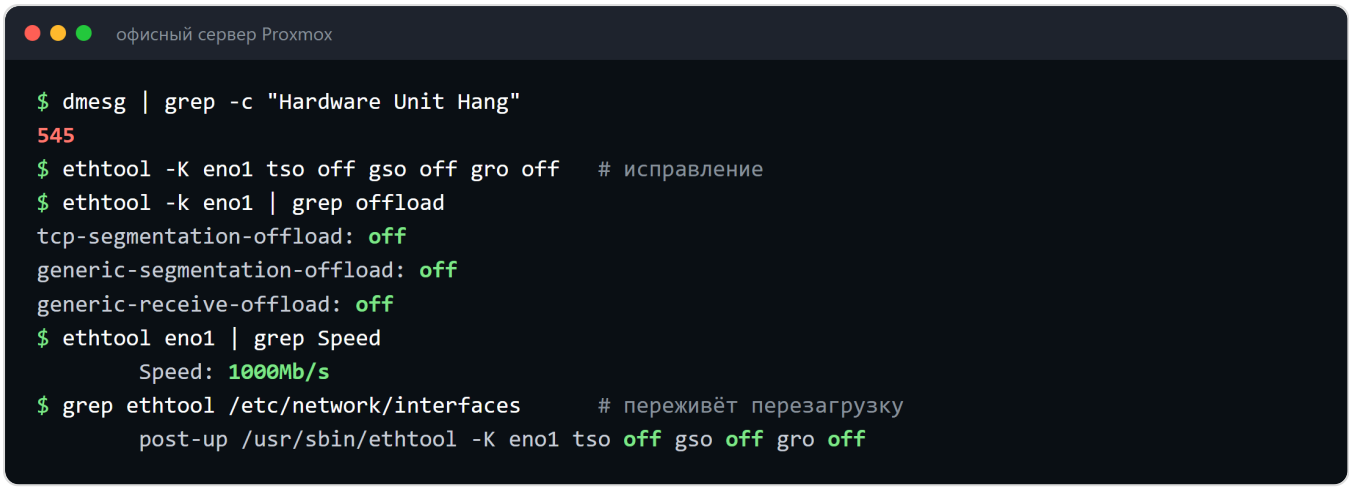

Real output from the backup server. Last backups, the failure on 3 Nov and the weekly check on 8 Nov. The log is in Russian. The client name is covered in red.

Real Yandex Cloud screenshot: the new server is created by Terraform (label managed-by: terraform). Name, address and ID are covered in red.

Console photo of the office backup server: the network card hangs under load (Detected Hardware Unit Hang). Addresses are covered in red.

The fix is permanent: hardware packet offload is off, the speed is 1000 Mb/s again, no new failures.

What you get in this gig

- I set up nightly backups of your server database and files to another provider, not where the server is.
- The backup is checked once a week by itself: the database is loaded and counted. A failure sends an alert.
- I write your new server as code (Terraform and Ansible). A move after a failure is a few commands.
- You get short notes: how to restore and how long it takes.
- An emergency restore of a server that is already down is separate work after a check of your backups.

Words in this document

Backup	a copy of the database and files on another server.
Hosting provider	the company that rents you the server. Here it is Beget.
Restore	bringing data from a backup back to a working server.
Terraform	a tool that creates cloud servers from a description in code.
Ansible	a tool that sets up a server from a description in code.

I do not show client names, server addresses or private data. I share them only with the client's permission. Icons: Tabler Icons, MIT license.
